Introduction

Over the last 3-4 years a formal organizational framework has been developed for evaluating the vulnerabilities of species and ecological systems to climate change (Glick et al., 2011). This framework assumes that the vulnerabilities of species or systems are a function of three main components – their exposure, sensitivity, and adaptive capacity (Figure 1):

*Exposure* – an estimate of how much change in climate (or other stressors) a species or system may be exposed to.

*Sensitivity* – the extent to which a species or system is likely to be responsive to or affected by changes in exposure.

*Adaptive capacity* – the ability of a species or system to adapt to and accommodate changes in exposure to stressors.

Downscaled analyses for the Northeast Region have shown that there is likely to be a degree of intraregional variation in how the climate may change over this century (e.g., Hayhoe et al. 2006). Exposures of systems or species will, therefore, also vary geographically. If the vulnerabilities of ecological resources are to be understood, this variation in exposure must be taken into account. This report presents information from the literature describing how the exposures of northeastern species and systems may change and vary geographically over this century. This is not intended to be an exhaustive analysis of future climate change. Rather, it uses existing data to provide expert panel and habitat workgroup members who are assessing vulnerabilities with background information describing likely climate futures. As they build or evaluate vulnerability assessments for selected habitats across the region, workgroup members can use the figures and tables presented in this report to assess how climatic changes and exposures may vary within and across the region.

The data have been gathered from two sources – the Northeast Climate Impacts Assessment (NECIA), and the web-based tool, ClimateWizard. NECIA (2006) was a major effort to describe plausible climate futures in the Northeast by statistically downscaling 3 Global Circulation Models (GCMs) to a 1/8° scale. The results were presented in a project report (NECIA, 2006), several scientific papers (e.g., Hayhoe et al. 2006 and 2007), and in an interactive website (http://www.northeastclimatedata.org/). ClimateWizard is a web-based interactive tool (http://www.climatewizard.org/) developed by The Nature Conservancy and the Universities of Washington and Southern Mississippi. It uses various combinations of the output of 16 GCMs to statistically downscale information to a 12km grid scale. Both sources provide the most recent and
thorough downscaled analyses of how the climate may change in the Northeast Region over the remainder of this century.

The southern boundary of the NECIA study area included the southern states of the NEAFWA area. However, for some variables (temperature, precipitation, evapotranspiration, soil moisture, snow cover days, drought, runoff, and stream flow) it excluded the southern portions of Virginia and West Virginia. ClimateWizard was used to fill this gap in coverage for the first two variables.

The temperature and precipitation metrics that can be addressed using ClimateWizard do not exactly match those that can be derived from the NECIA data-set (for example, the NECIA upper emissions estimates (Nakienovi et al. 2000) are based on the A1Fi emissions scenario, while ClimateWizard generally uses the A2 scenario). However, they are close enough for an acceptable match for the purposes of vulnerability assessment. Furthermore, the NECIA analyses cover a wider range of variables (temperature, precipitation, growing seasons, stream flow, snow cover, etc.) than are available in ClimateWizard, which is restricted to temperature and precipitation. We used both analytical tools to develop a comprehensive appraisal of how northeastern climatic and climate-related parameters will likely change over this century.

The data presented in this report do not include sea level rise estimates for the region. These will be provided in a separate document.
Exposure Information

The results of both downscaling analyses for the northeastern region are shown in Table 1 and in Figures 2 through 24. Table 1 presents the key, biologically relevant findings of the NECIA study for the region. Figures 2 through 6 describe how temperature and precipitation regimes are expected to alter over the next decades assuming low and a high (or medium-high) emissions scenarios. Figures 7 and 8 present NECIA results on how growing season and plant hardiness zones may alter. Figures 9 and 10 describe anticipated changes in evapotranspiration and soil moisture content. Figures 11 and 12 show projected changes in the characteristics of future snow cover in the region and Figure 13 projects future drought frequencies. Figures 14 through 19 project future changes in stream flow, runoff and low flow periods over the remainder of the century, while Figures 20 through 24 use ClimateWizard analyses to project temperature and precipitation changes for the states of Virginia and West Virginia.

Figure 1. Vulnerability assessment organizational framework.
Table 1. Projected changes in key climate indicators for the periods 2035-2064 and 2070-2099 (NECIA, 2006).
